

Routing Protocol

Distance Vector Routing

- i.e. Bellman-Ford and Ford Fulkerson
- Each router maintains a routing table indexed

Distance Vector Routing

(a) A subnet. (b) Input from A, I, H, K, and the new routing table for J.

To	A	I	H	K	New estimated delay from J ↓ Line	
A	0	24	20	21	8	A
B	12	36	31	28	20	A
C	25	18	19	36	28	I
D	40	27	8	24	20	H
E	14	7	30	22	17	I
F	23	20	19	40	30	I
G	18	31	6	31	18	H
H	17	20	0	19	12	H
I	21	0	14	22	10	I
J	9	11	7	10	0	–
K	24	22	22	0	6	K
L	29	33	9	9	15	K

JA delay is 8	JI delay is 10	JH delay is 12	JK delay is 6
---------------	----------------	----------------	---------------

Vectors received from J's four neighbors

New routing table for J	
8	A
20	A
28	I
20	H
17	I
30	I
18	H
12	H
10	I
0	–
6	K
15	K

(b)

Delay measured from J to all neighbors

Distance Vector Routing (2)

-Count to Infinity Problem

- Rapidly to good news, but leisurely to bad news

A	B	C	D	E	
•	•	•	•	•	Initially
	1	•	•	•	After 1 exchange
	1	2	•	•	After 2 exchanges
	1	2	3	•	After 3 exchanges
	1	2	3	4	After 4 exchanges

(a)

A	B	C	D	E	
•	1	2	3	4	Initially
	3	2	3	4	After 1 exchange
	3	4	3	4	After 2 exchanges
	5	4	5	4	After 3 exchanges
	5	6	5	6	After 4 exchanges
	7	6	7	6	After 5 exchanges
	7	8	7	8	After 6 exchanges

(b)

The count-to-infinity problem.

Split Horizon

- In [computer networks](#), [distance-vector routing protocols](#) employ the split horizon rule which prohibits a router from advertising a route back out the interface from which it was learned. Split horizon is one of the methods used to prevent [routing loops](#) due to the slow convergence times of [distance-vector routing protocols](#).

Route poisoning

- **Route poisoning** is a way to prevent [routing loops](#). [Distance-vector routing protocols](#) in [computer networks](#) use route poisoning to indicate to other routers that a route is no longer reachable and should be removed from their routing tables. A variation of route poisoning is [split horizon with poison reverse](#) whereby a router sends updates with unreachable [hop](#) counts back to the sender for every route received to help prevent routing loops.

Link State Routing

- Distance Vector routing was used in the ARPANET until 1979, when it was replaced by “Link State Routing”.

Link State Routing

Each router must do the following:

1. Discover its neighbors, learn their network address.
2. Measure the delay or cost to each of its neighbors.
3. Construct a packet telling all it has just learned.
4. Send this packet to all other routers.
5. Compute the shortest path to every other router.

Dijkstra's Algorithm can be used to find the shortest paths to every routers.

Learning about the Neighbors

(a) Nine routers and a LAN. (b) A graph model of (a).

(a)

(b)

Measuring Line Cost

A subnet in which the East and West parts are connected by two lines.

Swap between CF and EI time after time....! problem

Building Link State Packets

(a)

		Link		State		Packets	
A		B		C		D	
Seq.		Seq.		Seq.		Seq.	
Age		Age		Age		Age	
B	4	A	4	B	2	C	3
E	5	C	2	D	3	F	7
		F	6	E	1		

E		F	
Seq.		Seq.	
Age		Age	
A	5	B	6
C	1	D	7
F	8	E	8

(b)

(a) A subnet. (b) The link state packets for this subnet.

Building Link State Packets

- When to build them
 1. Periodically at regular intervals
 2. When some event occurs.
 - Line or Neighbors going down or coming back

Distributing the Link State Packets

Source	Seq.	Age	Send flags			ACK flags			Data
			A	C	F	A	C	F	
A	21	60	0	1	1	1	0	0	
F	21	60	1	1	0	0	0	1	
E	21	59	0	1	0	1	0	1	
C	20	60	1	0	1	0	1	0	
D	21	59	1	0	0	0	1	1
